Brandon Chen MATH 445 HW 4 Due Wednesday 4/25 12 A,D,E 13 A,C

12A Prove theorem 12.5 (The SSS similarity theorem). [Hint: Use the similar triangle construction theorem to construct triangle $\Delta D'E'F'$ that is similar to ΔABC , but with $\overline{D'E'}\cong \overline{DE}$. Then use the hypothesis and a little algebra to show that $\Delta D'E'F'\cong \Delta DEF$

Theorem 12.5: If $\triangle ABC$ and $\triangle DEF$ are triangles such that $\frac{AB}{DE} = \frac{AC}{DF} = \frac{BC}{EF}$, then $\triangle ABC \triangle DEF$

By theorem 12.4, we can construct a triangle $\Delta D'E'F'$ similar to ΔABC with side length $D'E'\cong DE$.

Then by construction of similar triangle, $\frac{AB}{D'E'} = \frac{BC}{E'F'} = \frac{BC}{E'F'}$

By transitive property of similarity, $\Delta DEF~\Delta D'E'F'$

Then by definition of similar triangle, $\frac{DE}{D'E'} = \frac{D'F'}{D'F'} = \frac{E'F'}{E'F'}$

But we know that D'E' = DE

So
$$DE = D'E', D'F' = D'F', E'F' = E'F'$$

Then
$$\frac{AB}{DE} = \frac{AC}{DF} = \frac{BC}{EF}$$

12D CONVERSE TO THE ANGLE BISECTOR PROPORTION THEOREM: Suppose $\triangle ABC$ is a triangle and D is a point in the interior of \overline{BC} such that $\frac{BD}{DC} = \frac{AD}{AC}$. Prove that \overline{AD} is the bisector of $\angle BAC$

Let $\triangle ABC$ be a triangle, and let D be a point in the interior of \overline{BC} such that $\frac{BD}{DC} = \frac{AD}{AC}$

Assume for contradiction that \overrightarrow{AD} is not the bisector of angle $\angle BAC$

Then E be a point on \overline{BC} such that \overrightarrow{AE} is the bisector of $\angle BAC$

Then by theorem 12.9, $\frac{BE}{EC} = \frac{AB}{BC}$

We know by hypothesis that $\frac{AB}{BC} = \frac{BD}{DC}$

Then $\frac{BE}{EC} = \frac{BD}{DC}$

And
$$\frac{BD}{BE} = \frac{DC}{EC}$$

Both D, E on interior of \overline{BC}

Then either B * D * E * C

or B * E * D * C

Case: B * D * E * C

Then BD < BE, and $\frac{BD}{BE} < 1$

And DC > EC, and $\frac{DC}{EC} > 1$

This contradicts that $\frac{BD}{BE} = \frac{DC}{EC}$

Case: B * E * D * C

Then BD > BE, and $\frac{BD}{BE} > 1$

And DC < EC, and $\frac{DC}{EC} < 1$

This contradicts that $\frac{BD}{BE} = \frac{DC}{EC}$

Then \overrightarrow{AD} must be the angle bisector.

12E Prove that the three midsegments of a triangle yield an admissible decomposition of the triangle into four congruent triangles, each of which is similar to the original one and has one quarter the area.

Construct a triangle $\triangle ABC$

Let D be the midpoint of \overline{AB}

Let E be the midpoint of \overline{BC}

Let F be the midpoint of \overline{AC}

$$\frac{AD}{AB} = \frac{1}{2} = \frac{AF}{AC}$$

For triangle $\triangle ADF$, it has angle $\angle BAC \cong \angle DAF$

So by theorem 12.6, SAS similarity, $\triangle ADF \triangle ABC$

Using a similar argument for ΔDBE , ΔEFC , we find that

 $\Delta DBE \ \Delta ABC$, and $\Delta EFC \ \Delta ABC$

So $\triangle ADF$ $\triangle DBE$ $\triangle EFC$

So by definition of similar triangles $\frac{AD}{DB} = \frac{AF}{DE} = \frac{DF}{BE}$

Since length AD = DB, then AF = DE and DF = BE

So by SSS congruence, $\Delta ADF \cong \Delta DBE$

Similarly, we show that $\Delta EFC \cong \Delta ADF \cong DBE$

For triangle ΔDEF , it is formed by shared side lengths with the other triangles.

We get that $DF \cong DF$, $DE \cong DE \cong AF$, and $FE \cong FE \cong AD$

Then $\Delta DEF \cong \Delta ADF \cong DBE \cong EFC$

And $\triangle DEF \triangle ADF \triangle DBE \triangle EFC \triangle ABC$

13A Use the idea suggested by figure 13.13 to give a proof of the pythagorean theorem. [Hint: bacuse the only figure given to you by the hypothesis is an arbitrary right triangle, first you have to explain how a figure like the one in the diagram can be constructed and justify any claims you make about relationships that the diagram suggests.]

Construct a right triangle $\triangle ABC$ with side lengths AB=a, BC=b, AC=c and let side length AC=c be the hypotenuse.

On \overrightarrow{BC} , take point D such that BD = a + b

Through point D, there exists a line ℓ parallel to \overline{AB} , take point E on ℓ such that DE = b, E on the same half plane as A

Then $\angle CDE = 90$, is right

And $\triangle CDE$ is a triangle with $CD = a = AB, \angle CDE = \angle ABC, DE = b = BC$

So by SAS congruence, $\Delta CDE \cong \Delta ABC$

So
$$CE = AC = c$$

 $\angle BCA, \angle ACE, \angle ECD$ form a linear triple, so $\angle BCA + \angle ACE + \angle ECD = 180$

We know that $\angle ECD \cong \angle BAC$

So $\angle BCA + \angle ACE + \angle BAC$

So $\angle ACE \cong \angle ABC$, is right angle.

So for $\triangle ACE$, AC = c = CE, and $\angle ACE = 90$

 $\overline{AB} \parallel \overline{DE}$ by construction,

So points ABDE form a trapezoid.

Let \overline{AB} , \overline{ED} be the bases of the trapezoid.

then ABDE has height a + b and bases with lengths a, b

Then ABDE has area $\frac{1}{2}[a+b]*[a+b] = \frac{a^2+b^2+2ab}{2}$

 $\Delta ABC, \Delta CDE, \Delta ACE$ are an admissible decomposition of ABDE

So the area $\alpha(ABDE)$ is equal to $\alpha(ABC) + \alpha(CDE) + \alpha(ACE)$

For right triangle $\triangle ABC$, let $\overline{BC}=b$ be the base, and the height be $\overline{AB}=a$, then it has area $\frac{1}{2}ab$

And since $\triangle ABC \cong \triangle CDE$, then $\alpha(CDE) = \frac{1}{2}ab$

For right triangle $\triangle ACE$, let side \overline{AC} be the base, and let \overline{CE} with s, so it has area $\frac{1}{2}c^2$

Then
$$\frac{a^2+b^2+2ab}{2} = \frac{1}{2}ab + \frac{1}{2}ab + \frac{1}{2}c^2$$

Then $a^2 + b^2 = c^2$

13C Prove theorem 13.2 (the converse to the pythagorean theorem). [Hint: Construct a right triangle whose legs have lengths a, b and show that it is congruent to ΔABC .]

Theorem 13.2: Suppose $\triangle ABC$ is a triangle with side lengths a, b, c. If $a^2 + b^2 = c^2$, then $\triangle ABC$ is a right triangle, and its hypotenuse is the side of length c

By contradiction, assume $\triangle ABC$ is a triangle with side lengths a, b, c and $a^2 + b^2 = c^2$, but $\triangle ABC$ not a right triangle

Construct another triangle ΔPQR with $PQ=a,QR=b,\angle Q$ is a right angle

By pythagorean theorem, $(PR)^2 = a^2 + b^2$

We know by hypothesis that $a^2 + b^2 = c^2$

So $PR^2 = c^2$, and PR = c

So PR = c = AC, so by SSS congruence, $\Delta ABC = \Delta PQR$

Then $\angle PQR \cong \angle ABC = 90$

But this contradicts that $\triangle ABC$ is not a right triangle.

Then $\triangle ABC$ must be a right triangle, with hypotenuse AC=c
